GRUBS

Grubs are the larvae of Japanese beetles and can cause damage to the roots of your lawn primarily in the early fall. Although they can be found in the soils while spring planting, damage rarely occurs. All turf will have some grub population in the fall, generally below 10 grubs per square foot and this will not cause damage. When populations rise above this level, turf may come loose like fresh sod. When this happens, an application of grub killer will be needed, along with additional watering. (1 hour per day for 2 - 3 weeks) for complete recovery. For lawns with a chronic history of grub damage, our optional preventative Grub treatment is recommended.
